

Extra — Café Menu: Four More Items

Topic: Dictionaries inside dictionaries · **Course:** Extra Worksheet · **Time:** about 30 minutes

Your café menu holds three items. Tonight it grows to seven, and every price gets its own variable.

Keep these words handy: **dictionary**, **key**, **value**, **variable**, **f-string**.

1 · Read Your Own Code 👁️

```
starbucks = {
    "americano": {
        "price": 6000,
        "ingredients": ["coffee beans", "hot water", "ice"]
    },
    "peach ice tea": {
        "price": 3000,
        "ingredients": ["ice", "peach tea", "water"]
    },
    "apple pie": {
        "price": 4000,
        "ingredients": ["apple jam", "bread", "suger"]
    }
}

print("=== MENU ===")
for name, info in starbucks.items():
    print(f"{name} ..... {info['price']} won")
```

How many lines print under `=== MENU ===` ? Why that many?

`starbucks["apple pie"]["price"]` gives you which number? Which key did each `[ ]` use?

2 · Plan Four New Items

Write four things your café will sell. Any prices you like.

Name	Price (won)	Three ingredients

Every new item must have: Circle one: price only · price and ingredients · ingredients only

Why does the loop above break if an item has no "ingredients" ?

3 · Type The Four Items

Copy this shape inside `starbucks`, once for each item you planned. Put a comma after the `}` of the item before it.

```
"mango juice": {  
  "price": 5000,  
  "ingredients": ["mango", "milk", "ice"]  
}
```

Press Run after each item. Seven lines under `=== MENU ===` means all four went in.

Write your fourth item here, the way you typed it:

4 · One Price, One Variable 💰

A variable holds one price, pulled out with the two keys you learned.

```
mango_juice_price = starbucks["mango juice"]["price"]
```

The variable name is the menu name with `_` instead of spaces, plus `_price`. Inside the `[ ]` the name keeps its spaces.

Write the seven variable lines you need, one per line:

- 1.
- 2.
- 3.
- 4.
- 5.
- 6.
- 7.

5 · Print The Prices

```
print(americano_price)
print(peach_ice_tea_price)
print(apple_pie_price)
```

Add one `print` line for each item you planned, then Run.

Your first three numbers are 6000, 3000, 4000. Write the four that follow:

- 1.
- 2.
- 3.
- 4.

One line printed the wrong thing, or an error appeared. What did you check first?

6 · Show Your Work 📷🎥

Open `main.py` so your seven menu items and your price lines are on screen, and press Run.

Record **one video** — one take, no stopping (a phone is fine). Show these in order:

1. Your code, and explain what your four new items are.
2. Your output, and explain what one variable line does.

Fill the blanks:

Today I built _____.

I built it using this code: _____.

In this code I used _____.

The hardest part was _____.

That part was hard because _____.

The most fun part was _____.

Something new I learned was _____.
